

What Are The Types Of Dental Implants?

A dental implant is an artificial tooth that replaces one or more permanent teeth that have been lost. The implant is a screw-like device inserted into the jawbone, which functions as an anchor for an artificial tooth called a crown. Wondering which dental implants near me will be suitable for you? Then it is time to learn about different types of implants. This article will go through various kinds of implants involving dental implants benefits.

1. Endosteal (Endosseous) Implants:

The most widely used form of dental implant is endosteal. Endosteal implants are commonly employed instead of a bridge or flexible denture. Screw (threaded), cylinder (smooth), and bladed endosteal implants are parts of Endosteal implants. The prosthodontist will help you decide which type of dental implant is best for you. However, endosteal implants are the most common and safe option. The first step in placing an endosteal implant is screwing it into the jawbone, which requires appropriate jawbone health and density. If your jawbone is genetically narrow, or if it is small, thinned, and worn down as a result of trauma or disease, you may not have enough bone to sustain an endosteal implant. A subperiosteal implant could be an option in this scenario.

2. Subperiosteal Implants:

Subperiosteal implants are yet another form of a dental implant. These implants are the most common replacement for endosteal implants. Subperiosteal implants are

not implanted into the jawbone; instead, they take possession of the bone underneath the gums. A post is attached to a metal structure placed under the gum to keep the frame in place. The gum helps gums heal faster—the poles which emerge from the gums anchor the artificial teeth. The surgery is performed if the patient's jawbone is insufficient for implant placement or doesn't like to undergo extensive dental surgery to add bone to the site. If you are one of these people, then a subperiosteal [dentist implant near me](#) is perfect.
