- The Dental Implant Process

Dental implants are not for everyone. You must be in good oral health and have enough healthy bone to support the dental implants. Your dentist will examine your teeth and take x-rays and molds of your teeth after an initial consultation. You must provide your dentist with a list of the prescription and non-prescription medications you take and you must answer several other vital medical questions, as dental implants typically require three surgical procedures. The process of the [Permanent Teeth Implants](#) is little more than extensive. Again the best thing is they are equal and even lesser to the Denture Implants Cost.

After a dose of local anesthesia, your dentist will make a small incision into your gum to uncover the bone in your jaw during your first dental implant surgery. Your dentist will drill a hole into the bone and will then place the dental implant before stitching the gum closed around the implant. Your dentist will usually take x-rays to ensure the proper placement of the implant. During the next few months, the bone slowly attaches to the implant.

Once the bone has attached to the implant, your dentist will perform the second phase of the dental implant surgery by providing you with local anesthesia and making another small incision to expose the dental implant. Your dentist will replace the protective screw installed during the first surgery with an abutment. After healing for a few weeks, your dentist will install a bridge or crown during the third and final phase of dental implant surgery.

- Potential Problems

Any dentist will agree that dental implant surgery often comes with problems or complications, many easily remediable. For instance, the implant may not attach to the bone adequately or you may get an infection. This rarely happens but is a potential problem to be aware of before undergoing dental implant surgery. Placing dental implants is not a straightforward process like a simple Invisalign tooth straightening procedure.
